Q. What is Hash code in Java?

A. A hash code in java is an integer value generated for every object by using the hashcode() method of the Object class. It is used to identify an object and helps java store and retrieve objects efficiently in collections like HashMap, Hashset and Hashtable.

Objects that are equal should have the same hashcode. However, two different objects can sometimes have the same hashcode, which is called a hash collision.

Example:

```
String s = "Hello";
System.out.println(s.hashCode());
```

> Every java object has a hashcode() method.
> It returns an integer value.
> It is used for faster searching and retrieval.
> Equal objects must have the same hash code.
